**PADLOCK CONSTRUCTION**

2

*Cut open view of the  
Yale Pin-tumbler Padlock*

**Pin-Tumbler Model**

The exterior appearance of Yale Pin-Tumbler Padlocks is a fair indication of their worth.

They are the strongest, most secure and dependable padlocks made.

The case is a very heavy bronze casting, capable of withstanding much abuse. The bronze inner block fits closely into the case and reinforces it.

The outside case and the inside block are both subjected to swedging or squeezing in dies under great pressure. This operation results in greater toughness, strength and accuracy.

There are two bolts, each independent of the other, one locking the toe and the other the heel of the shackle. The bolts are deadlocked, so that they cannot be pushed back out of position.

The shackle is made of a high carbon steel of great strength, casehardened to resist sawing or cutting. The shackle can also be furnished of phosphor bronze when so specified. This metal is usually preferred for outdoor use.

**Mechanism**

The key, when inserted in the plug, raises the pins to a common line, so that the plug may be turned. In turning the plug the two cams force back projecting lugs on the ends of the bolts. The bolts are thus forced back against the compression of piano wire springs to a point where they become disengaged from the notches in the heel and the toe of the shackle. The shackle is forced up and out by the action of a spring exerting pressure against the heel of the shackle.

**Padlocks with Special Markings**

The Nos. 830, 840, and 850 series of pin-tumbler padlocks can be furnished with special markings, such as insignia or monograms cast in the case.

These are frequently used by railroads, packing plants and other establishments where large numbers of padlocks are in use and it is necessary that they be easily identified. Particulars may be obtained upon application.

**PADLOCK CONSTRUCTION**

9

**Lever-Tumbler "Standard" Model**

**Design:** Yale "Standard" Model Lever-tumbler Padlocks are, next to the Pin-tumbler Padlocks previously described, the highest quality padlocks made. Their great strength and security are the result of careful design and exacting methods of workmanship.

The working parts are assembled and encased in a heavy bronze block which is set securely into the case and riveted thereto. Both the inside face of the case and the outside face of the block are accurately machined to secure a snug fit, and the rivets are polished flush with the outside of the case. This construction so reinforces the case that not even sledge-hammer blows will force the lock open.

The block containing the working mechanism is set into the case from the bottom of the padlock. The shackle, when locked, secures this block in place so that even were the holding rivets driven out, the padlock can not be opened except by its proper key.

**Materials:** All parts, inside and out, are of non-corroding material, such as bronze or nickel-bronze, to resist the action of the weather. The shackle is of tough cast bronze, "coined" or squeezed into shape in a steel die under high pressure. This coining process enables the shackle so treated to withstand a bending stress three hundred per cent greater than that which could be borne by a shackle of the same metal not so treated. The bronze metal of the case is made from a special formula which combines rugged strength with especial brilliancy of color. The keys are of nickel-bronze, "coined" in the same manner as the shackles. It has been found that keys so made cause practically no wear on the internal mechanism of the lock.

**Mechanism:** The interior mechanism consists of a locking-bolt engaging with one end of the shackle normally held in the locking position by a spring; a projection or "fence-pin" prevents the withdrawing of the bolt from the locked position. A series of lever-tumblers, each with a "gating" or slot at the end, are mounted on a shaft, and normally held by springs in such positions as to prevent the entrance of the "fence-pin" into the "gating." When the proper key is inserted, the bittings set the respective tumblers so that the "gatings" are all in line, and continued revolution of the key then withdraws the locking-bolt from the shackle. The free end of the shackle is then automatically forced up and out of the case by the action of a spring-controlled plunger.
